9. Heinrich Hertz first observed the photoelectric effect in 1887. He detected a current when light fell on a metal surface. In later research scientists measured the work function  $\phi$  of several metals. What is meant by work function? (a) **(1)** To measure the work function, the scientists used a phototube, consisting of a metal (b) cathode and anode in an evacuated tube. Light falling on the cathode produced a current in the circuit. Light falling on cathode Vacuum Phototube Explain the production of this current. Use the terms photon and photoelectron in your explanation.

**12.** A fluorescent lamp consists of a glass tube containing a small amount of mercury vapour. When the lamp is switched on the mercury atoms emit photons of ultraviolet (UV) radiation. A phosphor coating inside the tube converts this radiation into visible light.

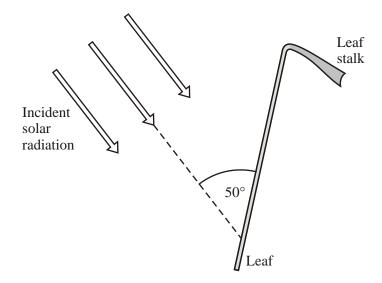

When a UV photon hits the coating it excites an electron into a higher energy level. As the electron falls back down, it emits a photon of visible light.

| (a) | (i)  | Add labelled arrows to the following electron energy level diagram for an atom of the phosphor coating, to illustrate this process. Start with the absorption of a UV photon and end with the emission of a photon of visible light. |     |  |  |

| Most physicists believe that light can behave as both a wave and a particle. Name a property of light which shows it can behave as a wave. |
| (1)  |

In 1916, Millikan published the results of an experiment on the photoelectric effect. This proved that light also behaves as particles.

He shone **monochromatic** light onto plates made of different types of metal.

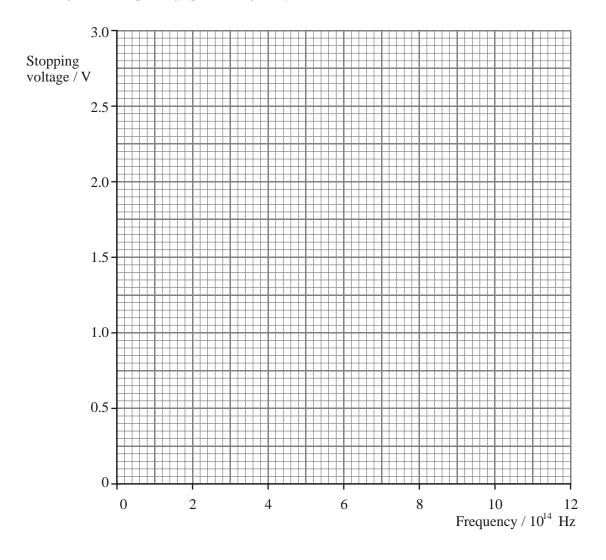

| What is meant by the term <b>monochromatic</b> ? |     |
|--|-----|
|  |     |
|  |     |
|  | (1) |

When the light hit the plates, photoelectrons were produced. Millikan found the potential difference that was just large enough to stop these electrons being released. He also investigated how this stopping voltage varied with the frequency of light used.

The table below shows the results of an experiment like Millikan's using sodium as the metal plate.

| Stopping voltage V <sub>s</sub> /V | Frequency of light $f/10^{14}$ Hz |
|------------------------------------|-----------------------------------|
| 0.43                               | 5.49                              |

| Photons of energy 3.17 eV are shone onto atoms in lithium vapour. Mark on the diagram, and   |
| label with a T, the transition which could occur.  (1  |

One way to study the energy levels of an atom is to scatter electrons from it and measure their kinetic energies before and after the collision. If an electron of kinetic energy 0.92 eV is scattered from a lithium atom which is initially in the -5.02 eV level, the scattered electron can have only two possible kinetic energies.

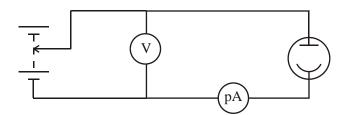

State these two kinetic energy values, and explain what has happened to the lithium atom in each case. (You should assume that the lithium atom was at rest both before and after the collision.)

**25.** The diagram shows apparatus for an experiment on the photoelectric effect.

Monochromatic radiation strikes the cathode C and photoelectrons are emitted towards the anode A. When a potential difference V is applied, a current I is measured on the very sensitive ammeter. Data can also be obtained with the polarity of the supply reversed. Using this apparatus, graph (a) below was obtained. After making a change to the incident radiation, graph (b) was obtained.

What can be deduced about the incident radiations from

**33.** The intensity of the light falling on the photocell shown in the diagram below controls the electric current flowing in a circuit.

An electron is sometimes released when a photon hits a metal surface. This is known as the photoelectric effect and can be expressed mathematically by the Einstein equation.

$$hf = \phi + \frac{1}{2}mv_{\text{max}}^2$$

| Show that the energy of a photon of light of frequency $6.0 \times 10^{14}$ Hz is about $4 \times 10^{-19}$ J. |     |
|--|-----|
|  |     |
|  | (1) |

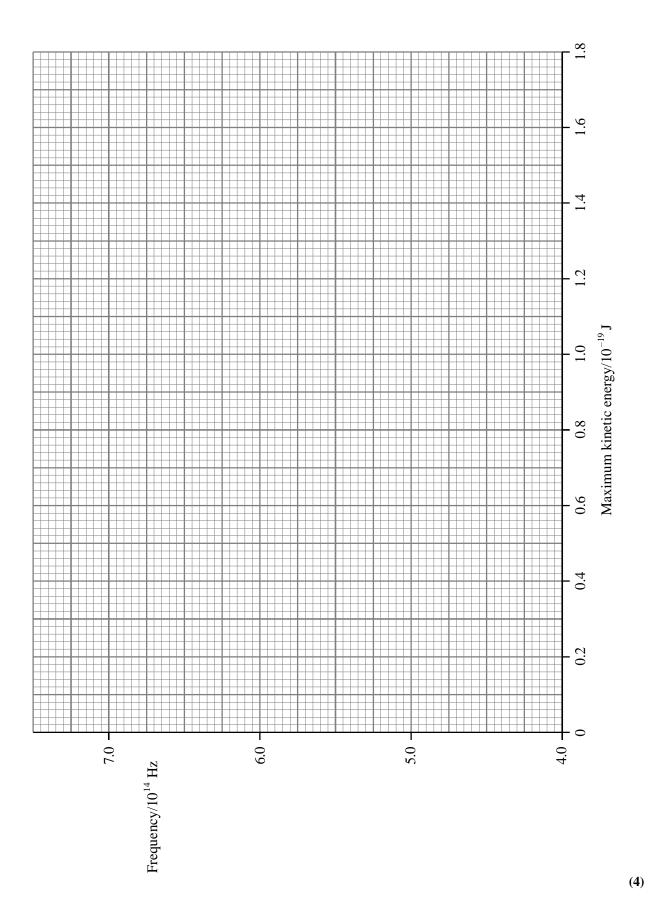

A student is investigating the photoelectric effect and selects light of various frequencies to shine on to a metal surface. Using his experimental data, he calculates the maximum kinetic energy of the electrons emitted from the surface. The results are given below.

| Frequency/10 <sup>14</sup> Hz | Maximum kinetic<br>energy/l0-19 J |
|-------------------------------|-----------------------------------|
| 7.0                           | 1.65                              |
| 6.5                           | 1.29                              |
| 6.0                           | 0.96                              |
| 5.5                           | 0.65                              |
| 5.0                           | 0.30                              |

Plot the points on the grid below. Add the line of best fit.

The Einstein equation can be rearranged to give

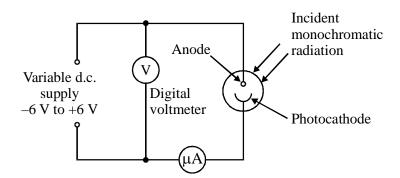

$$f = \frac{\phi}{h} + \frac{\frac{1}{2}m\upsilon_{\max}^2}{h}$$

| Use the graph you have plotted to find a value for <i>h</i> .  |     |

|   | Stopping potential =      |     |

**(2)** 

If the wavelength and intensity of the incident radiation is kept constant, a graph of the current I through the photocell against applied p.d. V is as shown.

Mark a letter S on the graph to show the stopping potential.

The photocathode is replaced with one whose metal surface has a greater work function. On the graph above, sketch how I would vary with V given that the wavelength and intensity of the incident radiation remain unchanged.

**36.** High temperatures in the Sun's atmosphere cause particles such as electrons and protons to be thrown out far into space. When these particles reach the Earth they can cause spectacular colour effects in the sky known as an aurora.

The particles interact with electrons in atoms in the upper atmosphere. As a result, coloured light is emitted. Green light of wavelength  $5.58 \times 10^{-7}$  m is given out from oxygen atoms and red light of wavelength  $6.48 \times 10^{-7}$  m from nitrogen.

## 37. Quantum Balls

BUCKYBALLS - spherical molecules made up of 60 carbon atoms - can behave like waves, blurring the boundary between the everyday world and the realm of quantum mechanics.

Markus Arndt and his colleagues at the University of Vienna sent buckyballs through a diffraction grating. A detector beyond the grating showed a clear interference pattern, where waves superimpose, indicating wavelike behaviour. "The interference pattern can only be explained if, in effect, each molecule goes through at least two of the openings" says Anton Zeilincer, who supervised the research.

Zeilinger predicts similar results with objects as large as viruses. He suggests that people think that quantum physics deals with small particles and classical physics deals with large things but that really the quantum world has no boundary.

Based on New Scientist Magazine, vol. 164, issue 2208.

**39.** Scientists from Leeds University are involved in an experiment at the South Pole to look for cosmic radiation from a supernova observed in 1987. Cosmic radiation consists of high energy particles from space.

Their equipment involves the following:

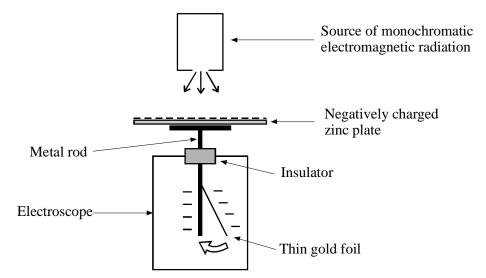

Cosmic radiation causes this plastic block to emit light. If this light enters the photomultiplier, photoelectrons are released and the signal is sent to a computer which records the event.

| A photomultiplier which has a photocathode made from antimony—caesium has a threshold wavelength of 700 nm. Explain why a photocathode has a threshold wavelength. |     |

**42.** The diagram shows apparatus which can be used to demonstrate the photoelectric effect.

The deflection of the thin gold foil is a measure of the charge stored on the zinc plate.

When ultraviolet light is directed towards the zinc plate, the thin gold foil gradually returns to the vertical.

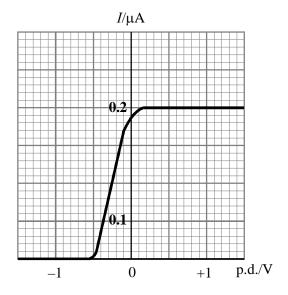

When red light is used the thin gold foil stays in the position shown.
